### ABSTRACT

**Objective:** This research aims to describe, analyze and synthesize the factors related to violence against women during the Corona epidemic.

**Method:** The method of this research is meta-analysis. The statistical population of the present study was composed of written documents, including theses, studies and articles published in scientific research journals in recent years on the issue of factors related to violence against women during the Corona period, among the published works available in the reliable and well-known Iranian scientific database (such as Noormags, Magiran, Irandoc, SID) and unpublished works of the library reference department of Mohaghegh Ardabili, Tehran, and Urmia universities, 26 documents in 51 research factors were selected. The information collected from each document and study was analyzed using CMA-2 and SPSS 22 software.

**Results:** The findings showed that the value of the chi-square index was 0.061 and the effect size value was calculated at 0.403 in the fixed model, and after examining these studies, 44 influencing factors were identified and their effects were evaluated as significant. All the mentioned values have been evaluated at the 95% confidence level.

**Conclusion:** The results of the present study showed that past studies have the power to explain and predict violence against women. These results can be a serious solution to improve marital relations during the pandemic.

**Keywords:** Corona, domestic violence, marital violence, meta-analysis.

### 1 Introduction

The world has gone through many epidemics so far. However, without a doubt, the *pandemic* of the new coronavirus (Covid-19) has been more distinct and different from other epidemics (Zareipour, Jadgeal, & Movahed, 2020). The high death rate and the fear and anxiety caused

by this virus have caused many other aspects of it to be paid less attention (Jannat Alipoor & Fotokian, 2022). One of the consequences of the emergence of the corona virus is a forced lifestyle change and unprecedented restrictions in people's lives (Bakhshi Mofrad Kashani, Asalani Mehr, & Abedi Elkhichi, 2021), of which home quarantine is one of them. The Covid-19 virus has caused a lot of economic,

social and family damage (Koohboomi, Ghamari, & Hosseinian, 2020), among which the issue of domestic violence is interesting and important. Quarantine and forced presence at home has increased the number of domestic violence and added domestic violence as another challenge to humanity today and has become a serious crisis for all countries (Miri Balajorshari & Mahmoudi, 2022). Many reports of the increase in *domestic violence* in different countries and even in European countries have been published so far. According to the World Health Organization, although home quarantine is a necessary and important way to deal with the coronavirus in the world, it has had consequences such as an increase in domestic violence and violence against women, an increase in fear, and economic and social pressures during the past weeks (Hudson, Lowenstein, & Hoenig, 2020). People who, in addition to the fear and anxiety of being infected by this virus, suffer from economic problems due to lack of work activities, suffer a lot of pressure, and this issue makes their tolerance threshold lower and violent behavior increases (Duncan et al., 2020). Many couples suffer more tension than others due to the longer time they spend with each other, not having individual time for themselves, and lack of knowledge about marital skills. Sometimes these tensions end in violence, and of course, most of the victims of these tensions are women (Hoseinnezhad, Elyasi, & Shahhosseini, 2020). These conditions have prompted experts to inform the public about domestic violence, its causes and control methods. Therefore, in this research, considering the extensive research that has been done in the field of domestic violence against women during the Corona period, we intend to conduct a meta-analysis of the past research.

Kooh Boomi, Ghamari and Hosseinian (2020) believe that the conditions caused by the coronavirus caused stress in people and caused them a lot of damage. Traumatic conditions such as post-traumatic stress may cause dysfunctional relationships and even violence between spouses. The findings obtained from the research of Kooh Boomi et al. (2020) showed that the direct and positive effect of psychological flexibility in the components of perception of controllability, and perception of justification of behavior on resilience is significant, and there is also a significant positive relationship between resilience and domestic violence. Also, resilience plays a mediating role in the relationship between the components of perception of controllability and perception of justification of behavior with domestic violence. According to the findings, it can be concluded that cognitive flexibility can predict resilience

and domestic violence against women (Koohboomi, Ghamari, & Hosseinian, 2020).

Therefore, it is necessary to investigate the level of domestic violence against women and the factors affecting it. In this research, we intend to investigate the level of domestic violence against women during the Corona period. By informing the relevant authorities, we can create an environment for employing, training and maintaining a safe, efficient and committed family, so that by reducing the costs caused by family disintegration and marital problems, a safe and secure life can be achieved.

In the changing context of marital relations in the family during the Corona period, studies indicate that marital problems and addressing family deficiencies have reached the optimal level (Asadi et al., 2023). However, Asadi et al. (2023) research, domestic violence against women is reported. In order to solve the contradiction resulting from such researches that have been conducted independently and in connection with domestic violence against women, meta-analysis statistical methods can be used. Meta-analysis converts the results of different studies into a common scale and examines the relationship between the characteristics of the studies and the findings with statistical methods. These contradictory results have also been seen in some other researches on the relationship of other variables with domestic violence against women in the Corona period, which prompts the researcher to conduct a meta-analysis on the conducted researches and present accurate and uniform results. The main goal of the current research is to meta-analytically examine the domestic and foreign researches on the increase of domestic violence against women in the period of Corona and to establish a connection between the studies and obtain a coherent result from the scattered results by using powerful statistical methods to answer the research questions (Asadi et al., 2023).

## 2 Methods

### 2.1 Study design Data Collection

The method of this research is meta-analysis. In this research, the focus is on the research done on a specific topic. Therefore, the society examined in this research is the final article (results of the conducted research) related to domestic violence against women during the pandemic. More precisely, this society consists of: Theses from some universities, articles published in prestigious domestic magazines and publications, and articles and abstracts related to this topic in several prestigious and well-known

Iranian scientific sites (such as Noormags, Magiran, Irandoc, SID) and prestigious universities. 51 factors and hypotheses were identified in 26 studies. The inferential statistics method was used to analyze the data. CMA2 software was used to check the information and answer the research questions in the inferential part.

### 2.2 Data Analysis

In this research, data analysis was used: meta-analysis models of fixed effects and random effects to obtain the discriminative and overall effect size; For studies of the effect size of Hedges' g; To check the publication bias from the funnel plots and Duval Tweedy's correction and fitting test; To check the number of missing studies from the fail-safe N test; Q and I2 tests were used to check the heterogeneity of studies. All these operations will be done using comprehensive meta-analysis software (CMA2) and the effect size combination method.

### 3 Findings and Results

Studies have shown that about violence against women during the Corona period, the statistical degree of the studied number of 51 factors (hypotheses) has been extracted from

26 studies, of which 3 hypotheses have emphasized the absence of a relationship and the rest have emphasized the existence of a relationship. H0 research has been rejected in 48 studies ( $2\chi$  equals 0.452), and the rest have been confirmed.

**Table 1**

*Descriptive statistics and calculation of chi-square of research hypotheses*

$\chi^2$	$F_o - F_e$	$F_e$	$F_o$	
0.452			48	H <sub>0</sub> Rejected
0.61	4/2	5/8	3	H <sub>0</sub> Accepted
60 Factors included				Total (60 factors)

From the comparison of Table 1 with the chi-square table, it is concluded that the  $2\chi$  of the rejected hypotheses with a value of 0.061 is smaller than the  $2\chi$  of the chi-square distribution table, so H0 is rejected, and the 1H of the research is at the level of 0.05 approved.

In this section, first, a funnel plot based on the standard error and accuracy indices in each of the studies is presented in uncorrected and corrected form; after that, the calculated results of the effect size for each of the studies are reported and also to examine the homogeneity test of the studies.

**Figure 1**

*Funnel chart based on the standard error index in the conducted studies*

**Figure 2**

*Funnel chart based on accuracy index*

According to [Figure 1](#) and [Figure 2](#), it can be seen that the studies used in this research are not symmetrically distributed around the average effect size, and the dispersion of studies around one side of the average indicates the presence of bias in the studies. Extensive studies appear at the top of the chart and small studies at the bottom. In order

to investigate and solve this, the method of arrangement and completion of double wall tweed has been used. This method calculates the missing studies on the left side of the graph, whose creation destroys the lattice mode. The results of using this method are reported in the [Table 2](#).

**Table 2**

*Arrangement and finishing method*

	Added	Constant effect			Random effect			Q-value
		Estimation Point	Lower bound	Upper bound	Estimation Point	Lower bound	Upper bound	
Observed		./43265	./45219	./52614	./49837	./36598	./48596	289/95675
Modified	9	./29863	./36215	./45219	./24589	./15326	./26538	518/56325

Based on the results listed in [Table 2](#), the number of missing studies is 9. And the point estimate in the fixed effects model using arrangement and completion method has increased from 0.43265 to 0.29863, also the point estimate in the random effects model has increased from 0.49837 to

0.24589. 0 has been changed. In other words, symmetry is created in this diagram by adding 9 studies to the left side of the average effect size.

**Figure 3**

Modified funnel chart based on the standard error index in the research question

**Figure 4**

Modified funnel chart based on accuracy index

Based on the results of Figure 3 and Figure 4, by adding 9 studies to the left side of the average skewness diagram, the distribution of studies is changed from asymmetric to symmetric. Added studies are shown as solid circles. Q-test was used to check the homogeneity of the studies. Q-value obtained equal to 6, which is significant with a probability of less than 0.05. Therefore, the null hypothesis based on the studies' homogeneity is rejected, which indicates that the

group of studies under investigation is heterogeneous. Also, the I2 index shows that 3.52165% of the effect size changes in all studies are due to the heterogeneity of the studies. For each of the studies, the effect size values based on Hedges g index (ordered from the smallest to the largest), lower limit, upper limit, z and p values in the 95% confidence level were calculated and their significance was evaluated through

Fisher's z test. The results of the calculations are shown in

Table 3.

**Table 3**

*Calculation of the effect size of its significance test for each of the studies (ranking based on the effect size values (N=60))*

45	addiction to Internet	0.742	0.320	163/1	3.447	0.001
46	Corona stress	0.360	0.219	0.486	4.782	0.000
47	Personality characteristics	0.743	0.361	1.124	3.818	0.000
48	Attachment Styles	0.370	0.206	0.514	4.237	0.000
49	Economic factors	0.496	0.282	0.710	4.541	0.745
50	Cognitive flexibility	0.520	0.144	0.895	2.713	0.007
51	Resilience	0.370	0.206	0.514	4.237	0.000

In Table 3, the first column shows the researcher's name, in the second column, the following variables are reported for the researches. The Hedges g index presented in the next column is considered as the effect size in each study, which was calculated using CMA-2 software. The next columns have lower and upper limit values, at 95% confidence

intervals, for z for each study, as well as the probability level assigned to the studies. Two fixed and random models have been used to check the overall significance of the effect size after combining the studies, the results of which can be seen in Table 4.

**Table 4**

*The results of combining the effect size of the studies and their significance*

Model	Index			Z	p	Mean effect size	
	G	Lower bound	Upper bound			+	-
Const.	0.403	0.249	0.328	2.775	0.000	0.663	0.425
Random	0.598	0.558	0.627	1.542	0.000		

As can be seen in Table 4, the value of the overall effect size for studies in the fixed effects model was estimated at 0.403 with 95% confidence in the range of 0.249 to 0.328 based on the Hedges g index. For the random effects model, it was estimated at 0.598 with 95% confidence between 0.558 and 0.627. In order to check and determine the publication bias of the combined studies, the safe incomplete

number index has been used. The results of publication bias show that the number of 441 missing studies with an effect size equal to zero is needed to turn the above significant result into a non-significant result and the obtained P value reaches the alpha limit.

In the research conducted in the field of violence against women during the Corona period, there were 51 factors in the statistical sample, and the influencing and correlated variables with the researched violence against women include: Social subjugation, family atomization, educational crisis, leisure crisis, income level, dimensions of sexual schemas, women's employment, men's education, family's economic base, patriarchal tradition, difficulty in emotional regulation, distress intolerance, marital conflicts, behavioral systems, self-control, lack of legal reforms, schema therapy, socio-economic problems, spouse addiction, age, number of children, cyber space, education level, corona crisis, marital intimacy, restraint, marital conflict, knowledge, attitude, skill, problem solving skill, patriarchy, gender socialization, neglect, individual dimension, couple dimension, urbanization dimension, family dimension, meta-family dimension, patriarchal beliefs, internet addiction, corona stress, personality traits, attachment styles, cognitive flexibility and resilience.

In the analysis of the results of rejecting or confirming H0 in the existing research using the statistical index of chi-square, the calculated value is equal to 0.61, which is less than the critical chi-square, the calculated value is significant at the level of 0.05.

#### 4 Discussion and Conclusion

Violence against women is a social category with many different natures, examples, and even causes and contexts of occurrence in different societies (Mirjafari et al., 2022). Today, legislators seek to create a legal structure to fight against all types of violence against women maximally, and various international regulations have been established in this field (Aolymat, 2021). However, when this violence occurs at the level of the family institution, it is much more serious and critical; Because the angles of violence in the family are hidden from the public in most societies (Bright, Burton, & Kosky, 2020). In this research, the researcher seeks to meta-analyze the factors related to violence against women in the period of Corona.

The subject of the current research is a meta-analysis of factors related to violence against women in the period of

Corona. For this purpose, 26 documents with 51 factors and research hypotheses were selected from the databases of SID, Magiran, as well as the reference section of the libraries of different universities, and their required information was recorded in the meta-analysis checklist. Inferential analysis of data was analyzed using CMA-2 software. In this section, we refer to the calculated values of the effect size and the results obtained from the tests related to the publication bias and finally to the results of the probabilities in the research. In general, the z value calculated for all factors is significant at the level of  $\alpha < 0.05$ .

The examination of the Q-test showed that the studies under the composition are heterogeneous. The safe incomplete number index showed that there is bias in the studies. It is important to mention one point regarding the examination of the safe incomplete number test to eliminate the publication bias in the studies used; It is to pay attention to the zero hypotheses in this test so that the zero hypothesis of the safe incomplete number test indicates the existence of heterogeneity in studies, and this heterogeneity indicates the existence of a moderating variable (Ghaderzade & Abdollahzade, 2022). Therefore, if the significance value does not exceed 0.05, an error occurs, and this error, which is evident in all research questions due to the impossibility of adding a large number of research documents with zero effect size to the applied studies, significance is forced to be accepted. By the assumption of heterogeneity of the studies, the obtained results have been confirmed.

The review of studies has shown that out of 51 correlated factors, some studies had non-significant effects, and significant effects were reported for the rest (Basandeh, Haji Tabar Firoozjaei, & Foroughiniya, 2022; Mirahmadian et al., 2022; Miri Balajorshari & Mahmoudi, 2022; Mirjafari et al., 2022; Nemati, 2023; Nemati & Farajiha, 2023; Shirali, 2022).

In general, the results of the meta-analysis of studies on violence against women in the Corona period showed that the effective and correlated variables with violence against women in the Corona period, in which a positive and meaningful relationship has been confirmed, are:

Social subjugation, family atomization, educational crisis, leisure crisis, income level, dimensions of sexual schemas, women's employment, men's education, family's economic base, patriarchal tradition, difficulty in emotional regulation, distress intolerance, marital conflicts, behavioral systems, self-control, lack of legal reforms, schema therapy, socio-economic problems, spouse addiction, age, number of children, cyberspace, education level, corona crisis, marital intimacy, restraint, marital conflict, knowledge, attitude, skill, problem-solving skill, patriarchy, gender socialization, neglect, individual dimension, couple dimension, urbanization dimension, family dimension, meta-family dimension, patriarchal beliefs, internet addiction, corona stress, personality traits, attachment styles, cognitive flexibility, and resilience.
